# Electrons at the heart of modelling in LTPs

- **Modelling of low-pressure ccrf discharges in N<sub>2</sub>-H<sub>2</sub>**

Time-dependent hybrid (fluid+kinetic) code, with beam model for fast electrons

Results

- the coupling between fast/slow electrons
- the normalized ion flux
- ammonia production

- **Electron kinetics in dry-air pulsed plasmas**

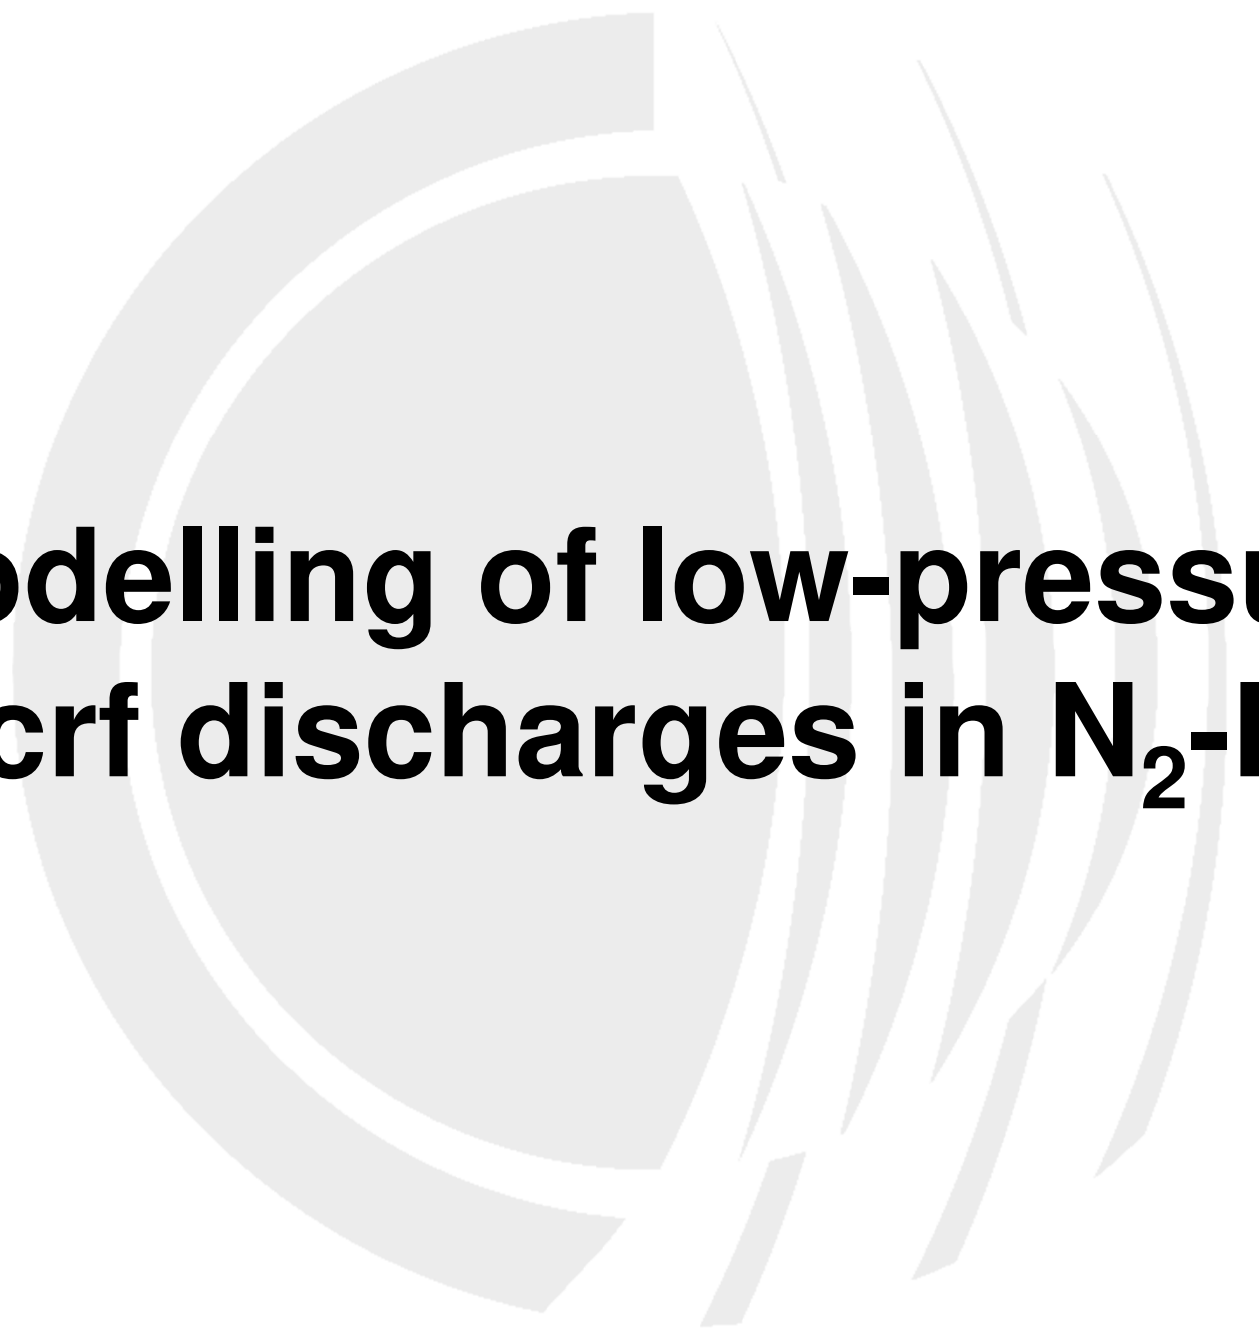

Formulations adopted in solving the EBE

- time-dependent solution
- quasi-stationary approach

Results in dry air (80%N<sub>2</sub> : 20%O<sub>2</sub>)

- step-fields ( $\tau_{\text{on}} \rightarrow \infty$ ) with different  $\tau_{\text{rise}} \sim 0 - 1 \mu\text{s}$
- typical discharge pulses at limited  $\tau_{\text{on}}$  and  $\tau_{\text{rise}} \sim \text{ns}, \mu\text{s}$

- **Final remarks**

# Modelling of low-pressure ccrf discharges in $N_2-H_2$

# Studies of low-pressure N<sub>2</sub>-H<sub>2</sub> plasmas

## Synthesis of ammonia

(surpassing the efficiency of the thermochemical Haber–Bosch process)

focus on the role of plasma-surface interactions

## Fusion research

use of N<sub>2</sub> to attenuate the local heat loads on tungsten divertors

- drawbacks
  - implantation of nitrogen and nitriding of plasma-facing materials
  - sputtering by energetic nitrogen ions, and formation of tritiated ammonia

## Technological applications

- deposition of thin films
- etching of organic low permittivity films
- surface treatment by nitriding of metals or semiconductors
- carbon nanotube functionalization
- catalyst pretreatment for carbon nanotube growth

## Planetology

laboratory simulation of the chemistry of Titan's atmosphere

N<sub>2</sub>/CH<sub>4</sub> ccrf discharges leading to the production of Tholins-analogues (solid aerosols)

Titan: artist's conception, *airspace*mag (2020)

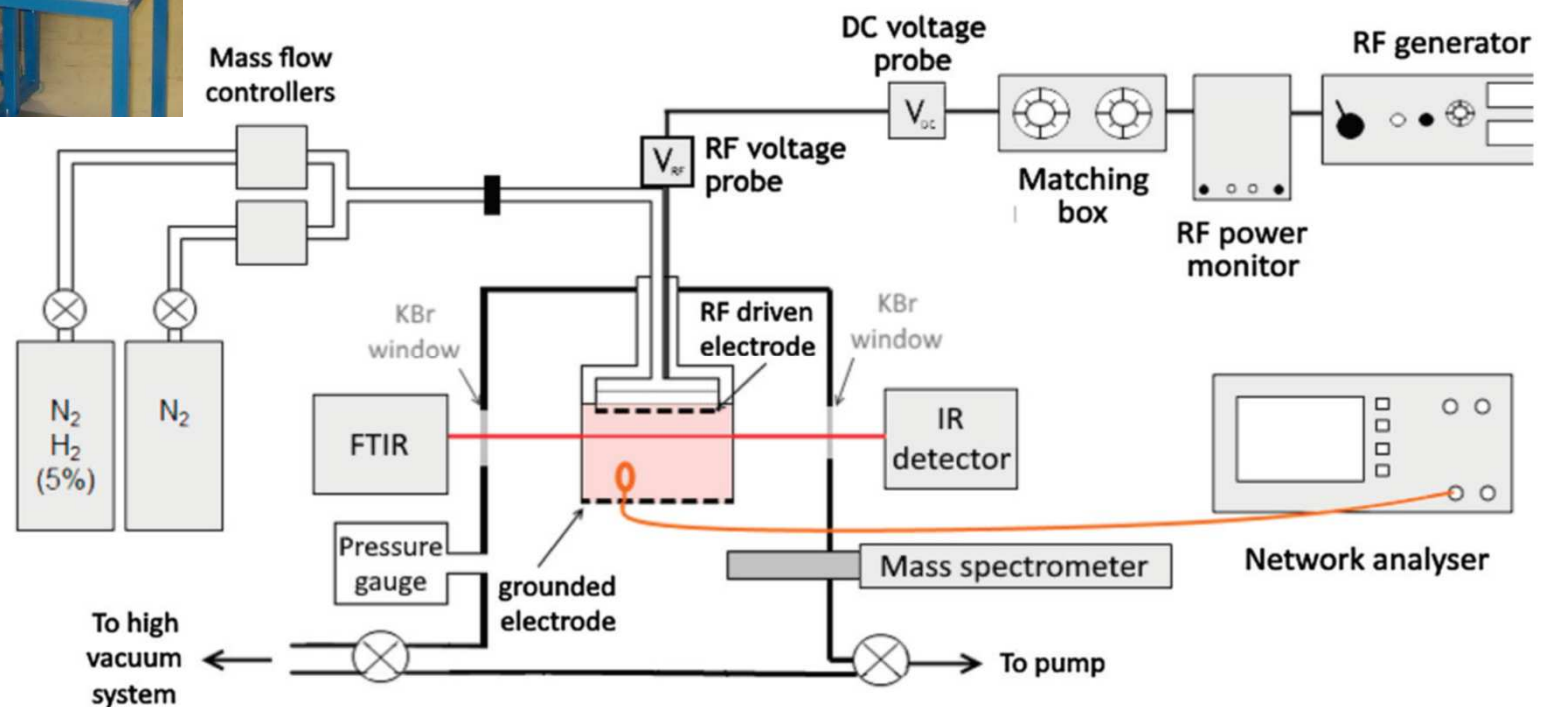

# CCRF discharges in N<sub>2</sub>-H<sub>2</sub> plasmas

## Working conditions

Chamber: SS + aluminium alloy ; 30x40 cm<sup>2</sup>  
N<sub>2</sub> – H<sub>2</sub> mixtures (up to 5% H<sub>2</sub>)  
 $P \sim 5 - 30$  W (@ generator)  
 $f = 13.56$  MHz  
 $p \sim 0.3 - 1$  mbar  
Flow rates  $\sim 10 - 70$  sccm

# The single-beam model for fast electrons

M Surendra et al Phys. Rev. A **41**, 1112 (1990)

M Goujon et al Thin Solid Films **475**, 118 (2005)

- fast electrons (with initial energy 1 eV) created at the walls by impingent positive ions

$$n_f u_{\perp f} = -\gamma j_+$$

- secondary electron yield adjusted to fit the experimental trend  $n_e = f(W_{\text{eff}})$

$$\gamma = \begin{cases} 0.09 & @ 0.5 \text{ mbar} \\ 0.06 & @ 0.92 \text{ mbar (less energetic ions reaching the wall)} \end{cases}$$

- particle and energy balance equations for the fast electrons are solved within an enhanced grid that resolves the space-charge sheath

$$\frac{\partial n_f}{\partial t} = -\nabla_{\perp} (n_f u_{\perp f}) + S_f$$
$$\frac{\partial (n_f \varepsilon_f)}{\partial t} = -\nabla_{\perp} (n_f u_{\perp f} \varepsilon_f) + n_f u_{\perp f} E_{\perp} - S_f^{\varepsilon}$$

# Adjusting the secondary electron yield

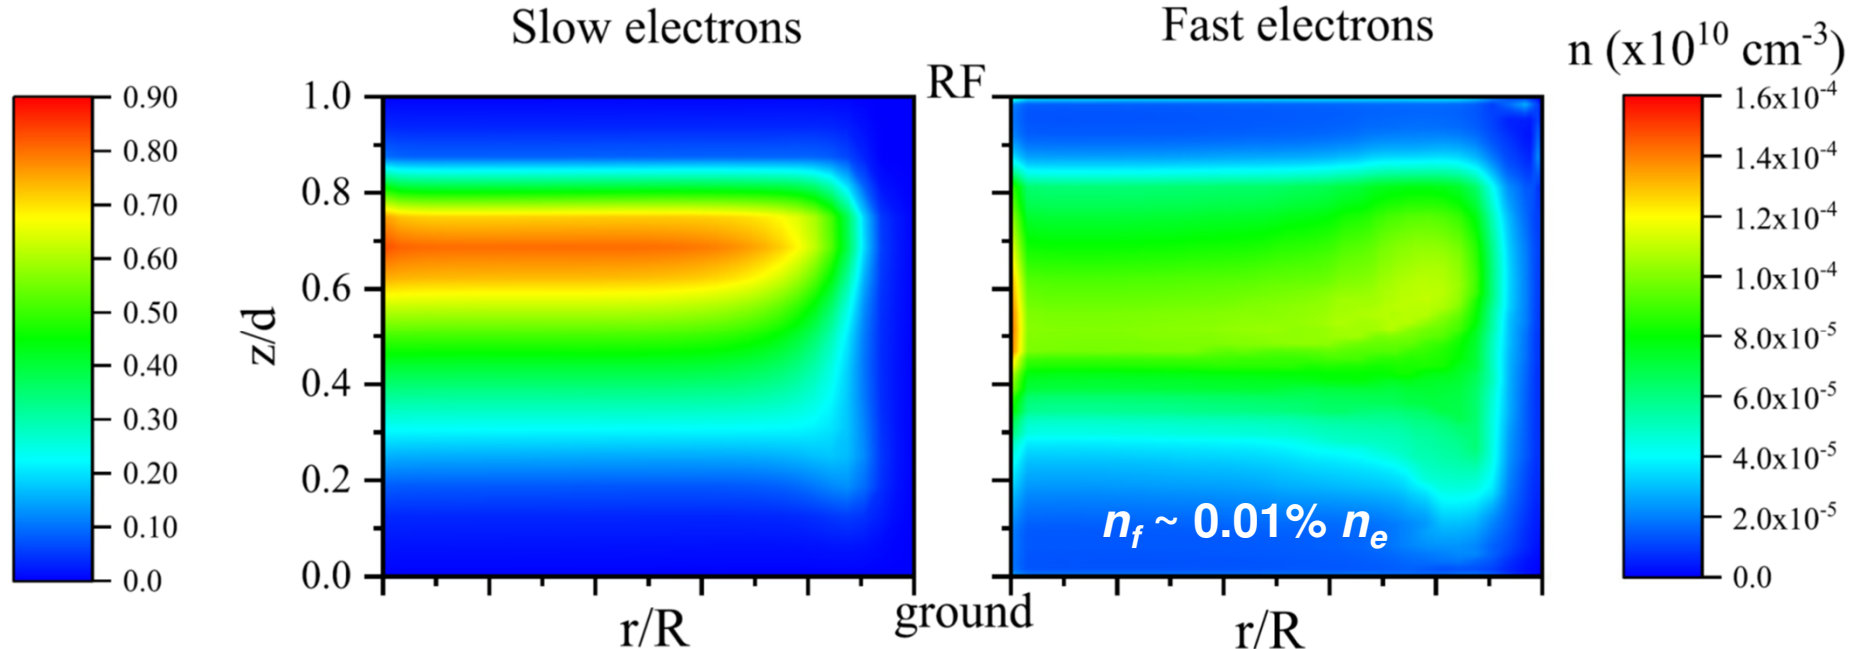

The electron density increases linearly at low power, exhibiting an exponential growth at higher power

The behavior of the self-bias potential is mostly linear, deviating from that trend when the secondary electron emission becomes significant

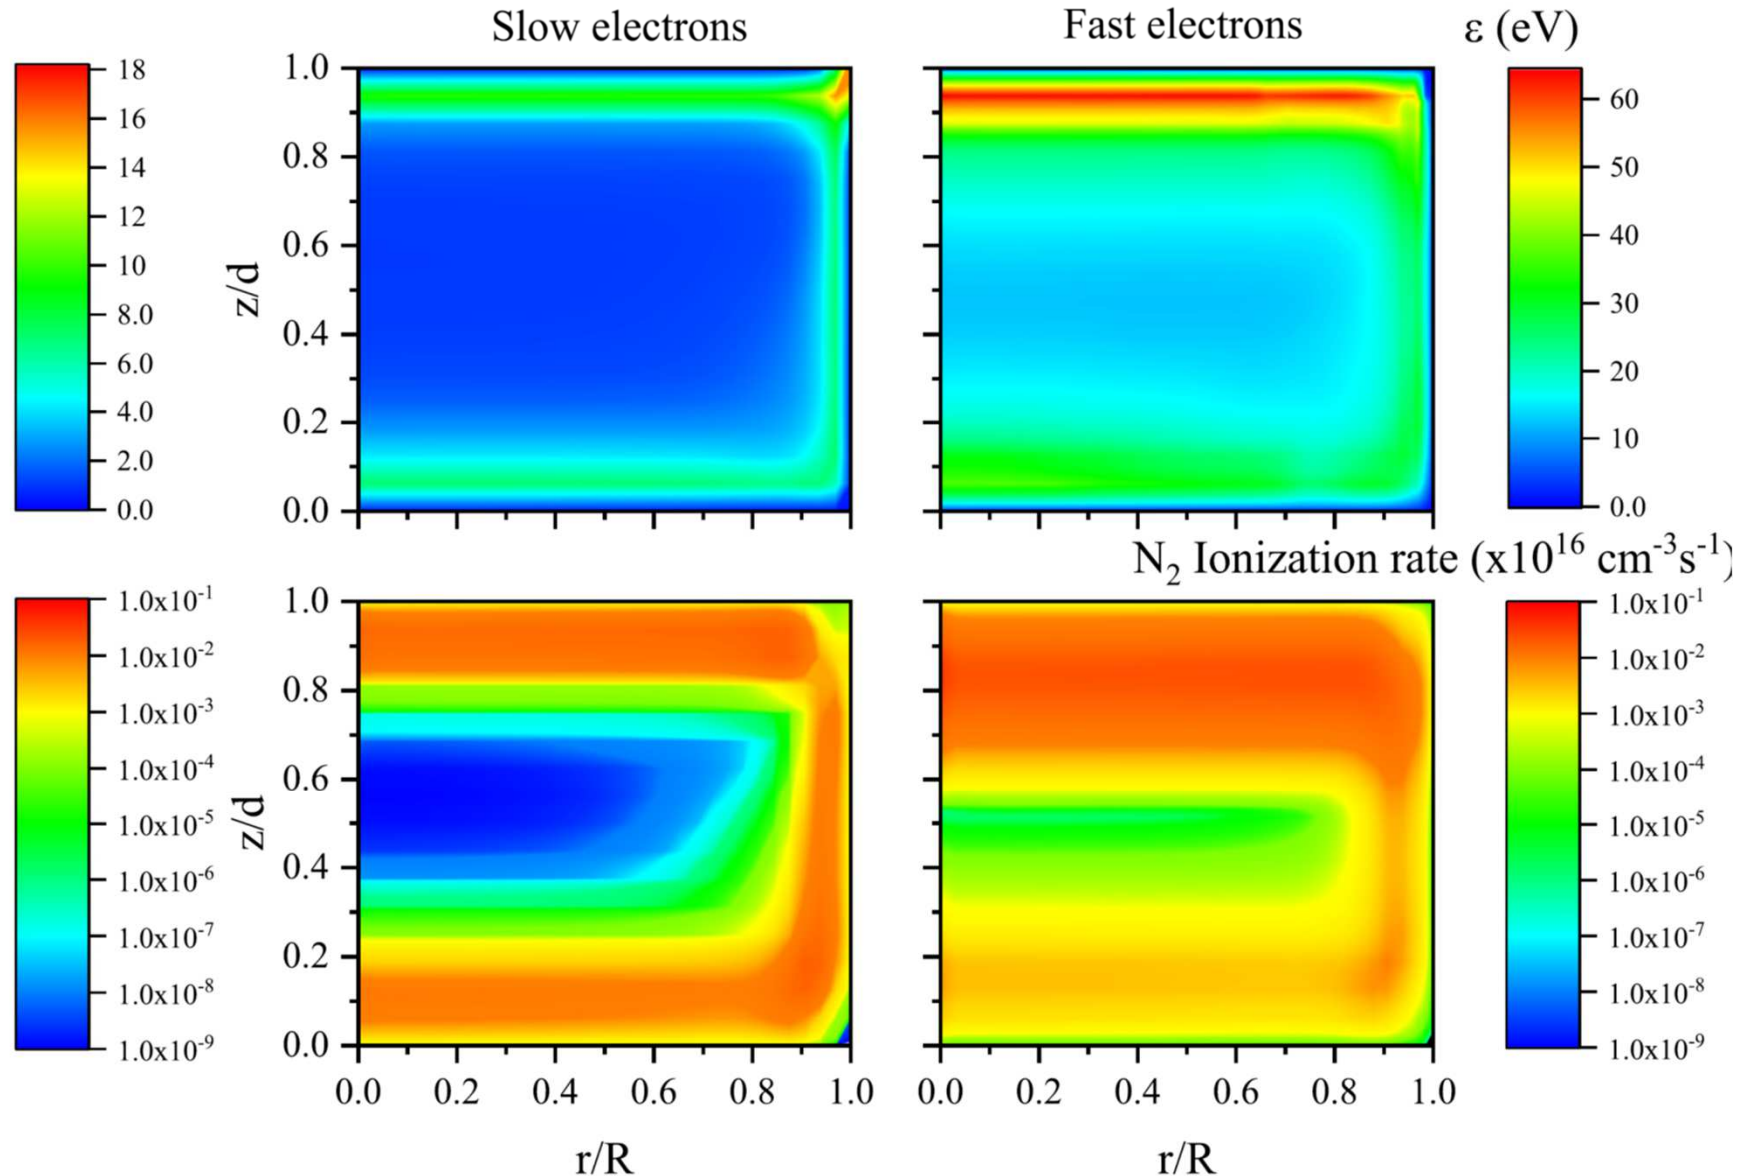

# The coupling between fast and slow electrons

- **Within the sheath, fast electrons**
  - are accelerated by the electric field
  - with  $\varepsilon_f > V_{ion}$  produce new beam electrons (flux increase; energy decrease)
- **Within the negative glow, the beam is dilute into the plasma**
  - ionization produces slow electrons
  - the beam energy is progressively lost to inelastic collisions

# Results for the three beams of fast electrons

5% H<sub>2</sub>, at 0.92 mbar and 11.5 W.

# Results for the normalized ion flux - I

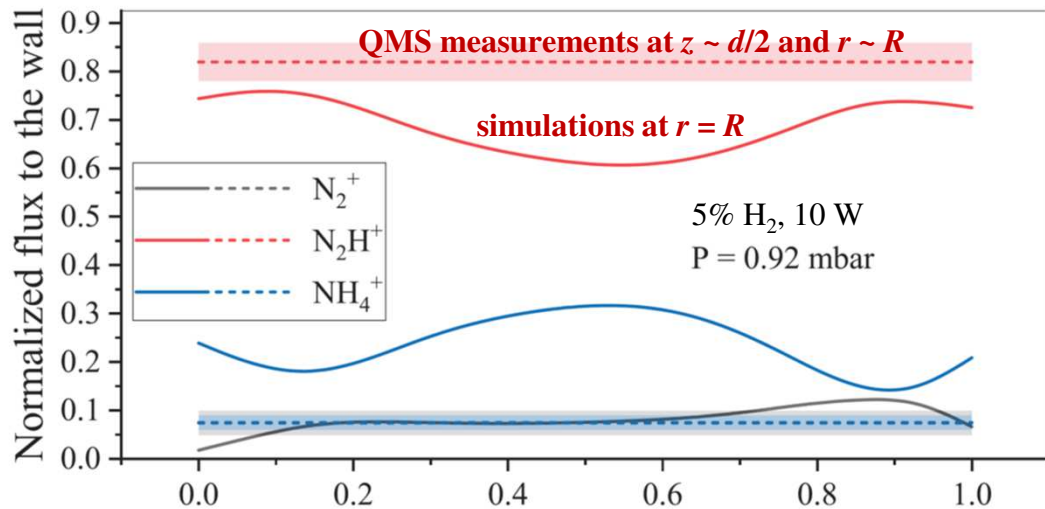

5% H<sub>2</sub>, at 0.92 mbar and 10 W.

The model reproduces adequately the global trends of the ion flux measurements

The most abundant ion is N<sub>2</sub>H<sup>+</sup>

# Results for the normalized ion flux - II

Model predictions underestimate the ionization rate in the bulk (high power)

The ions are mostly produced from the reaction chain

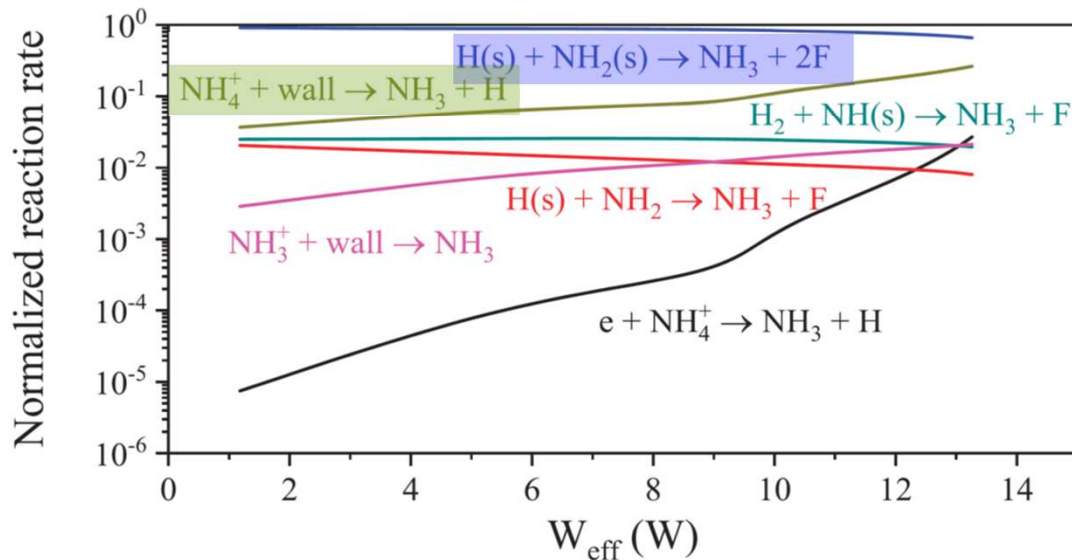

Because the ion-molecule reactions are very efficient the relative abundance of the ions is controlled by the efficiency of the e-ionization reaction

⇒ simple model for fast electrons

⇒ unprecise NH<sub>3</sub> production

# Results for ammonia production - I

5% H<sub>2</sub>, at 0.92 mbar and 10 W.

SS + **aluminium alloy** reactor

⇒ low reactivity surfaces

**overall low abundance of NH<sub>3</sub>**

# Results for ammonia production - II

**5% H<sub>2</sub>, at 10 W.**

Limited description / lack of additional mechanisms

- pressure-dependent surface reactivity
- vibrationally enhanced dissociative adsorption of N<sub>2</sub>
- spatially-resolved chemistry coupled to the fast electrons

# **Electron kinetics in dry-air pulsed plasmas**

A Tejero-del-Caz *et al* 2021 *Plasma Sources Sci. Technol.* **30** 065008

# Studies of time-dependent electron kinetics

## Motivation

- **Increasing interest in non-equilibrium LTPs created by pulsed discharges**, for different technological applications  
[plasma-assisted ignition and combustion; plasma chemical-conversion involving dry reforming, plasma pyrolysis and management of CO<sub>2</sub> ]
- **The voltage applied to gases** at intermediate-to-high pressures, during the nanosecond to microsecond time-scale typical of breakdown, **greatly affects the plasma parameters and composition**

## Efforts to study the time-dependent electron kinetics

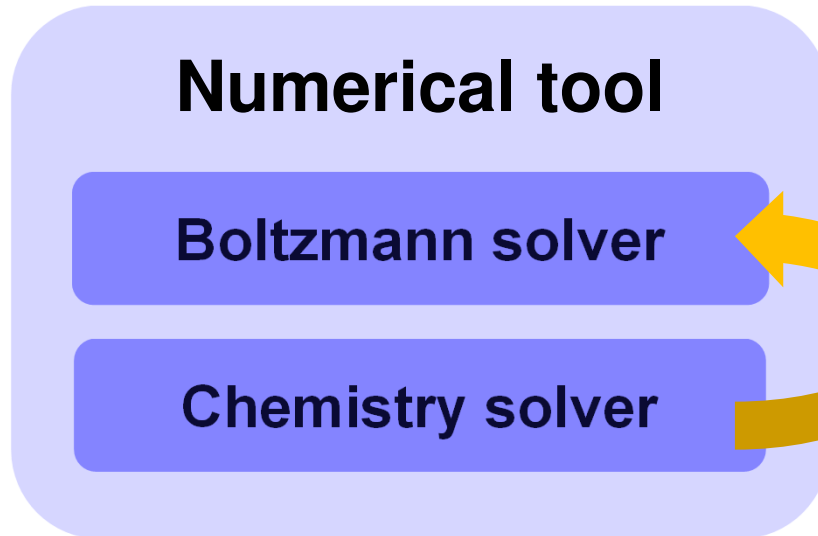

- **homogeneous plasmas excited by time-varying sinusoidal electric-fields**  
[Fourier-development of 2-term electron Boltzmann equation (EBE)]
- **discharges and afterglows** [solving the time-dependent EBE]  
+ coupling with heavy-particles balance equations (including VDF) or discharge models
- **electron diffusion in time-dependent  $ExB$  fields** [Monte Carlo simulations]
- **time or the space-time analyses of electron relaxation**  
[2-term / multi-term EBE and Monte Carlo simulations]

Seminal works of Wilhelm, Capitelli and co-workers

Recent works of Colonna et al [Colonna et al (2020); Pietanza et al (2020)]

# Studies of time-dependent electron kinetics

**BUT...**

time description coupling  
assuming approximations

- using effective source terms for the electron-impact creation of excited species  
[Carbone et al (2016)]
- considering a quasi-stationary description for electrons by solving a time-independent form of the EBE for chosen values of  $E/N$   
[Simek and Bonaventura (2018), Wang et al (2018), Heijkers et al (2019)]

## Limitations in publicly available tools for solving the EBE ?

- ELENDF, BOLOS, METHES, Magboltz (DC electric fields)
- BOLSIG+, EEDF, LoKI v1.0.0 (DC and HF electric fields)
- MultiBoltz (multi-harmonic model for intense microwave and THz fields)

# The LisbOn Kinetics Boltzmann solver (LoKI-B v2.0.0)

(developed under MATLAB®)

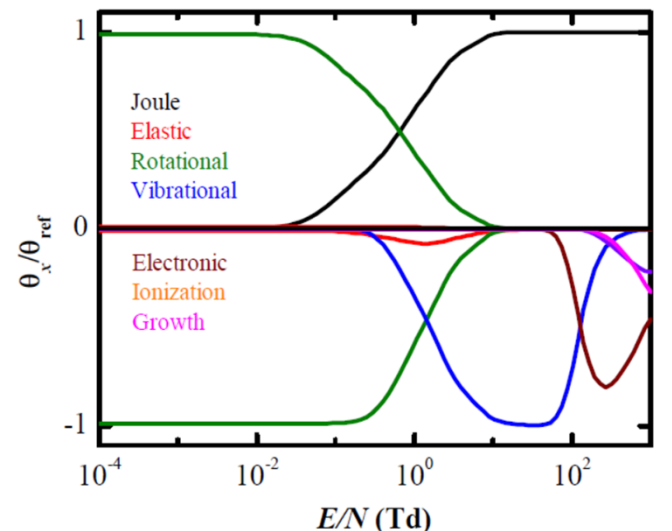

## LoKI-B

**OPEN SOURCE**

<https://github.com/IST-Lisbon/LoKI>

- solves the time and space independent form, or the **time-dependent form**, of the two-term electron Boltzmann equation
- includes e-e collisions, CAR operator, and growth models for the electron density.

## The LisbOn Kinetics Boltzmann solver

was developed as a response to the need of having an electron Boltzmann solver easily addressing the **simulation of the electron kinetics in any complex gas mixture** (of atomic / molecular species), describing first and second-kind electron collisions with **any target state** (electronic, vibrational and rotational), characterized by **any user-prescribed population**.

A. Tejero-del-Caz *et al* Plasma Sources Sci. Technol. 30 (2021) 065008

# Formulation adopted - I

## Time-dependent electron Boltzmann equation

- two-term approximation
- homogeneous (space-independent) description

$$F(u, \theta, t) \simeq n_e(t) [f(u, t) + f^1(u, t) \cos \theta]$$

- variation of the electron density due to non-conservative binary events (ionization and attachment)

$$\begin{aligned} \frac{dn_e(t)}{dt} &= \langle \nu_{\text{eff}} \rangle(t) n_e(t) \\ \langle \nu_{\text{eff}} \rangle(t) &\equiv \langle \nu_{\text{ion}} \rangle(t) - \langle \nu_{\text{att}} \rangle(t) \end{aligned}$$

$$\frac{1}{N} \sqrt{\frac{m_e}{2e}} \sqrt{u} \frac{\partial f(u, t)}{\partial t} + \sqrt{\frac{m_e}{2eu}} \frac{\langle \nu_{\text{eff}} \rangle(t)}{N} u f(u, t) + \frac{1}{N} \sqrt{\frac{m_e}{2e}} \frac{\partial G(u, t)}{\partial u} = S(u, t)$$

# Formulation adopted - II

## Quasi-stationary electron Boltzmann equation

$$\frac{1}{N} \sqrt{\frac{m_e}{2e}} \frac{\partial f(u, t)}{\partial t} + \sqrt{\frac{m_e}{2eu}} \frac{\langle \nu_{\text{eff}} \rangle(t)}{N} u f(u, t) + \frac{1}{N} \sqrt{\frac{m_e}{2e}} \frac{\partial G(u, t)}{\partial u} = S(u, t)$$

# Results in dry air

## Working conditions

Dry air (80%N<sub>2</sub> : 20%O<sub>2</sub>) @  $p = 10^5$  Pa and 133 Pa ;  $T_g = 300$  K

Initial condition : Maxwellian EEDF at 300 K

Assuming

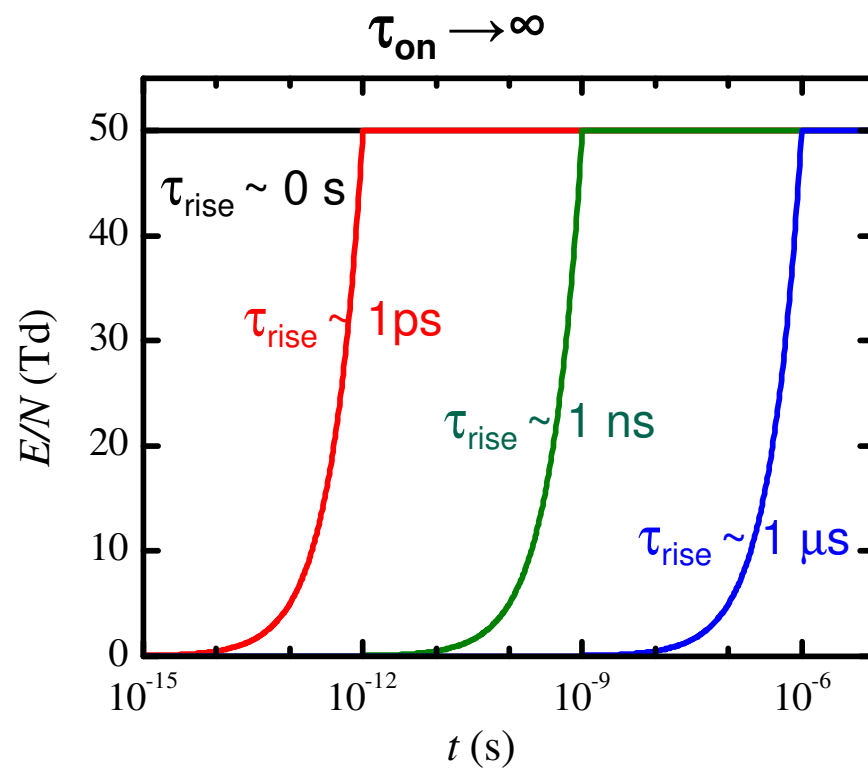

- **stationary neutral gaseous background**
- **no coupling with chemistry model**
- Boltzmann distributions at 300 K for the VDFs of N<sub>2</sub>(X,v=0-10) and O<sub>2</sub>(X,v=0-4)
- the continuous approximation to describe rotational excitations / deexcitations

Electron-scattering cross sections published at the IST-Lisbon database with LXCat

# Results in dry air

## Working conditions (cont)

Excitation by applying electric field pulses

# Results in dry air – step fields

The electron mean energy

$$\rho = 10^5 \text{ Pa}$$

The natural response time of the electrons at atmospheric pressure is of the order of  $\sim 10$  ps

The quasi-stationary approach holds for rise-times much larger than the characteristic evolution time of the EEDF

$$\tau_{\text{rise}} \gg \tau \simeq \frac{1}{\sum_k \frac{m_e}{M_k} \nu_{k,c}^{\text{el}}} \simeq \frac{5 \times 10^{17}}{N(\text{m}^{-3})}$$

At 1 atm and room temperature

$$\tau_{\text{rise}} \gg 2 \times 10^{-8} \text{ s}$$

# Results in dry air – step fields

The electron energy distribution function

$$\rho = 10^5 \text{ Pa}$$

# Results in dry air – field pulse

## The electron energy distribution function - I

$$E_0/N = 100 \text{ Td}$$

$$\tau_{\text{rise}} \sim 10^{-9} \text{ s}$$

# Results in dry air – field pulse

## The electron energy distribution function - II

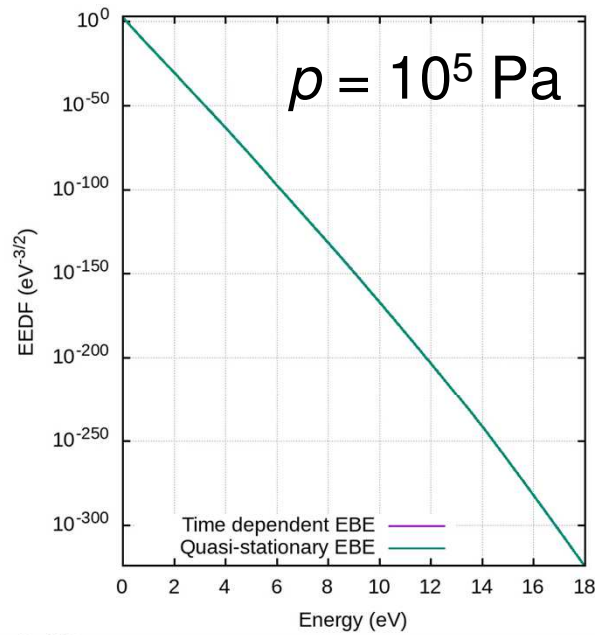

$$E_0/N = 100 \text{ Td}$$

$$\tau_{\text{rise}} \sim 10^{-9} \text{ s}$$

# Results in dry air – field pulse

## The electron energy distribution function - III

$$E_0/N = 100 \text{ Td}$$

$$\tau_{\text{rise}} \sim 10^{-6} \text{ s}$$

# Results in dry air – field pulse

## Criterion for quasi-stationary simulations

The quasi-stationary approach holds for

$$\tau_{\text{rise}} \gg \tau \simeq \frac{1}{\sum_k \frac{m_e}{M_k} \nu_{k,c}^{\text{el}}} \simeq \frac{5 \times 10^{17}}{N(\text{m}^{-3})} \implies \tau_{\text{rise}} N \simeq \text{const}$$

		$\rho = 10^5 \text{ Pa}$ and $\tau = 2 \times 10^{-8} \text{ s}$	$\rho = 133 \text{ Pa}$ and $\tau = 2 \times 10^{-5} \text{ s}$
$\tau_{\text{rise}}$	$10^{-9} \text{ s}$	Fail	Fail
$\tau_{\text{fall}}$	$10^{-8} \text{ s}$	Fail	Fail
$\tau_{\text{rise}}$	$10^{-6} \text{ s}$	OK	Fail
$\tau_{\text{fall}}$	$10^{-5} \text{ s}$	OK	Fail

At low pressure, there is no “instantaneous” collisional transfer of the E-field energy into the gas, hence the slow temporal increase of the electron mean (kinetic) energy

## Relevance of the electron kinetics in the predictive modelling of LTPs Two examples

- **Modelling of low-pressure ccrf discharges in  $N_2-H_2$** 
    - a proper treatment of electron secondary emission is key to obtain realistic predictions for the plasma / discharge parameters
    - when adopting fluid simulations, a beam model for fast electrons improves the description of the electron particle and energy distribution
    - the model reproduces adequately the global trends of the ion flux measurements
    - model predictions for  $NH_3$ 
      - \* are in good agreement with measurements, as a function of power
      - \* could benefit from a better description and/or the inclusion of additional mechanisms as a function of pressure
- [the calculated spatial distribution of ions could also improve]

- **Electron kinetics in dry-air pulsed plasmas**

- excitation by electric-field pulses ( $\tau_{\text{rise}} \sim \text{ns to } \mu\text{s}$ ) at  $p = 133 \text{ Pa}, 10^5 \text{ Pa}$
- adopting (i) time-dependent formulation; (ii) quasi-stationary approach
- the quasi-stationary description
  - \* holds for high-collisionality and long rise-times ( $\tau_{\text{rise}} \sim \mu\text{s}$  at  $p_{\text{atm}}$ )
  - \* fails for fast risetimes ( $\tau_{\text{rise}} \sim \text{ns}$  for all  $p$ 's)
- similar results are obtained for  
long pulses / low pressures and short pulses / high pressures  
→ optimization of the pulse duration, depending on the gas pressure,  
to maximize electron energy absorption
- simulations were applied to a stationary neutral gaseous background  
The inclusion of the effects of heavy-particle interactions (e.g., VVs & VTs), in fully-coupled time-dependent Boltzmann-Chemistry calculations, can alter modelling predictions (especially beyond the  $\mu\text{s}$  scale and/or in multi-pulse scenarios).
